## Claim Objections

1. Claim 4 is objected to because of the following informalities: "amino siloxane" should be changed to – aminosiloxane --.

## Claim Rejections - 35 USC § 112

2. The following is a quotation of the second paragraph of 35 U.S.C. 112:

The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

3. Claims 4, 10 are rejected under 35 U.S.C. 112, second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention.

Claim 4 recites the limitation "the layer" in line 2. There is insufficient antecedent basis for this limitation in the claim.

Claim 10 recites the limitation "the core" and "the layer" in line 2. There is insufficient antecedent basis for this limitation in the claim.

## Claim Rejections - 35 USC § 103

- 4. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:
  - (a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.
- 5. Claims 1-20 are rejected under 35 U.S.C. 103(a) as being unpatentable over Hartley et al (US 4,853,737) and incorporated by reference Lentz (US 4,257,699) in view of Schlueter, Jr. et al (US 5,995,796).

Art Unit: 1762

Hartley discloses a method of making a fuser member having a support comprising the steps of providing a support (See column 8, lines 9-12); coating onto the support an organic solvent-based coating composition (See column 8, lines 4-6) comprising a fluorocarbon thermoplastic random copolymer, a curing agent having a bisphenol residue (See column 3, lines 5-11), a particulate filler containing a <u>combination</u> of (See column 6, lines 51-52) metal oxides such as zinc oxide, antimony oxide, tin oxide (See column 6, lines 42-53) and aminosiloxane (See column 2, lines 48-50; column 5, lines 27-46), the fluorocarbon thermoplastic random copolymer being commercially available terpolymers of vinylidene fluoride with hexafluoropropylene and tetrafluoroethylene (i.e. terpolymers having subunits of –(CH<sub>2</sub>CF<sub>2</sub>)x-, -(CF<sub>2</sub>CF(CF<sub>3</sub>)y-, – (CF<sub>2</sub>CF<sub>2</sub>)z-) such as Viton B (See column 3, lines 1-3); gradually raising the temperature of the coating composition from 20°C to 230°C for 12-24 hours and then curing at that temperature for 24 hours (See column 8, lines 26-33). It is well known in the art that Viton B contains about 61 % of vinylidene fluoride, about 17 % of hexafluoropropylene and about 22 % of tetrafluoroethylene, as evidenced by Eddy et al (US 5,017,432). See column 6, lines 4-6.

Hartley further teaches that one skilled in the art can compare the release of various cured fluoroelastomers containing the metal oxides to determine the <u>optimum metal oxide</u> or <u>combination</u> thereof and <u>concentrations</u> thereof. See column 6, lines 49-53.

Hartley fails to teach that the optimum metal oxide combination contains antimony doped tin oxide; and curing time for the coating composition at temperature from 20°C to 275°C is 5-10 hours.

As to antimony doped tin oxide, Schlueter, Jr. teaches that antimony doped tin oxides (optionally in a combination with other metal oxides such as zinc oxide (See column 4, lines 57-67; column 12, lines 4, 8)) added to a fluoroelastomer/aminosiloxane copolymer allows for a

Art Unit: 1762

stable resistivity virtually unaffected by changes in relative humidity and temperature and provides optimal conductivity (See column 10, lines 25, 40-68) for the filled copolymer (See column 4, lines 1-67; column 5, lines 1-17).

It would have been obvious to one of ordinary skill in the art at the time the invention was made to have used antimony doped tin oxides in a combination with zinc oxide for filling a fluoroelastomer/aminosiloxane copolymer of Hartley with the expectation of providing the desired stable resistivity and optimal conductivity, as taught by Schueter, Jr.

As to the curing time for the coating composition at temperature from 20°C to 275°C being 5-10 hours, one of ordinary skill in the art would know that curing time depends on materials of a coating composition. It is held that where the general conditions of a claim are disclosed in the prior art, it is not inventive to discover the optimum or workable ranges by routine experimentation. In re Aller, 220 F.2d 454, 456, 105 USPQ 233, 235 (CCPA 1955).

It would have been obvious to one of ordinary skill in the art at the time the invention was made to have determined by routine experimentation the optimum curing time (including claimed 5-10 hours) of an organic solvent-based coating composition of combination of Hartley and Schlueter, Jr. comprising a fluoroelastomer (containing about 61 % of vinylidene fluoride, about 17 % of hexafluoropropylene and about 22 % of tetrafluoroethylene), zinc oxide, antimony doped tin oxide, aminosiloxane and a bisphenol curing agent.

As to claim 2, Hartley further teaches that aminosiloxane is amino functional polydimethyl siloxane copolymer. See column 5, lines 27-45.

As to claim 3, Hartley further teaches that amino functional unit of polydimethyl siloxane copolymer is (aminoisopropyl)methyl (See column 5, lines 42-46) or aminopropyl (See column 11, lines 5-6).

Art Unit: 1762

It is held that compounds which are position isomers (compounds having the same radicals in physically different positions on the same nucleus) or homologs (compounds differing regularly by the successive addition of the same chemical group, e.g., by -CH2- groups) are generally of sufficiently close structural similarity that there is a presumed expectation that such compounds possess similar properties. In re Wilder, 563 F.2d 457, 195 USPQ 426 (CCPA 1977). See also In re May, 574 F.2d 1082, 197 USPQ 601 (CCPA 1978) (stereoisomers prima facie obvious). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have substituted (aminoisopropyl)methyl of Hartley with its position isomer (aminopropyl)methyl with the expectation of maintaining the desired benefits since a presumed expectation that both compounds possess similar properties.

As to claims 4, 5, 6, Hartley further teaches that aminosiloxane has total concentration in a coated layer of 1-15 percent. See column 5, lines 60-68; column 6, lines 1-8.

As to claims 7, 8, Hartley further teaches that a mixture of fillers containing zinc oxide has total concentration of 10-100 weight percent based on weight of the cured fluoroelasomer. See column 6, lines 3-8, 45-46.

As to claim 9, Hartley further teaches that the fluoroelasomer is cured by bisphenol curing agent. See column 3, lines 5-55.

As to claim 10, Hartley further teaches that the fuser member may optionally contain resilient layers (a cushion layer) between a core and a coating layer. See column 8, lines 9-19.

As to claim 11, Hartley further teaches that the fluoroelasomer is nucleophilic addition cured. See column 3, lines 5-15.

As to claims 12-14, Hartley further teaches that <u>any known fluoroelasomers</u> derived from terpolymers of vinylidene fluoride with hexafluoropropylene and tetrafluoroethylene (i.e.

Art Unit: 1762

terpolymers having subunits of –(CH<sub>2</sub>CF<sub>2</sub>)x-, -(CF<sub>2</sub>CF(CF<sub>3</sub>)y-, –(CF<sub>2</sub>CF<sub>2</sub>)z-) can used for preparation of fuser roll surfaces. See column 2, lines 39-44; column 3, lines 1-4. It is well known in the art that a fluoroelasomer having x number of 49 mole %, y number of 10 mole % and z number of more than 40 mole %, is commercially available as "3M THV". It would have been obvious to one of ordinary skill in the art at the time the invention was made to have used commercially available fluoroelastomer "3M THV" for coating a fuser member with the expectation of providing the fuser member with the desired benefits, as taught by Hartley.

As to claims 15, Schlueter, Jr. further teaches that antimony doped tin oxide is added to a fluoroelastomer/aminosiloxane copolymer in an amount 5-65 weight percent of total solids. See column 11, lines 57-65.

As to claims 16, antimony doped tin oxide has 6.5 weight percent of antimony. See column 11, line 49.

As to claims 17-20, Hartley further teaches that non-crosslinked fluoroelasomers that have been used for preparation of fuser roll surfaces are known materials such as those described in Lentz (incorporated by reference in Hartley). See column 2, lines 39-44. The known materials of Lents may be represented as mixtures of fluoroelasomers having molecular weight in the range of 1,000-200,000 (See column 9, lines 21-26) such as Viton B and polytetrafluoroethylene (fluorinated resin) (See column 8, lines 46-56, 65-67; column 9, lines 5-6).

However, Hartley and incorporated by reference Lentz fail to teach that ratio of Viton type fluoroelastomer to PTFE in the mixture is between 1:1 to 50:1.

One of ordinary skill in the art would know that some toners could be only fixed at high temperatures that would require high heat stability of a fuser member. It is well known in the art that addition of PTFE to the Viton type fluoroelastomer would increase heat stability of the

resulting mixture. Therefore, amount of PTFE in the mixture is result-effective variable in a

method of making the fuser member. It is held that where the general conditions of a claim are

disclosed in the prior art, it is not inventive to discover the optimum or workable ranges by routine

experimentation. In re Aller, 220 F.2d 454, 456, 105 USPQ 233, 235 (CCPA 1955).

It would have been obvious to one of ordinary skill in the art at the time the invention was

Page 7

made to have determined by routine experimentation the optimum amount of PTFE (including

claimed ratio between 1:1 to 50:1) in a mixture with Viton type fluoroelastomer depending on

toner to be fixed.

Conclusion

6. Any inquiry concerning this communication or earlier communications from the examiner

should be directed to Elena Tsoy whose telephone number is (703) 605-1171. The examiner can

normally be reached on 9:00-5:30.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor,

Shrive Beck can be reached on (703) 308-2333. The fax phone numbers for the organization

where this application or proceeding is assigned are (703) 872-9310 for regular communications

and (703) 872-9311 for After Final communications.

Any inquiry of a general nature or relating to the status of this application or proceeding

should be directed to the receptionist whose telephone number is (703) 308-0661.
